Contents

Foreword **7**

Prefaces **11**

Acknowledgments **17**

1 Building Abstractions with Functions **21**
1.1 The Elements of Programming . . . 23
1.1.1 Expressions . . . 24
1.1.2 Naming and the Environment . . . 26
1.1.3 Evaluating Operator Combinations . . . 27
1.1.4 Compound Functions . . . 29
1.1.5 The Substitution Model for Function Application . . . 31
1.1.6 Conditional Expressions and Predicates . . . 34
1.1.7 Example: Square Roots by Newton's Method . . . 38
1.1.8 Functions as Black-Box Abstractions . . . 42
1.2 Functions and the Processes They Generate . . . 46
1.2.1 Linear Recursion and Iteration . . . 47
1.2.2 Tree Recursion . . . 52
1.2.3 Orders of Growth . . . 57
1.2.4 Exponentiation . . . 59
1.2.5 Greatest Common Divisors . . . 62
1.2.6 Example: Testing for Primality . . . 64
1.3 Formulating Abstractions with Higher-Order Functions . . . 69
1.3.1 Functions as Arguments . . . 70
1.3.2 Constructing Functions using Lambda Expressions . . . 75
1.3.3 Functions as General Methods . . . 79
1.3.4 Functions as Returned Values . . . 84

2 Building Abstractions with Data **91**
2.1 Introduction to Data Abstraction . . . 94
2.1.1 Example: Arithmetic Operations for Rational Numbers . . . 95
2.1.2 Abstraction Barriers . . . 98
2.1.3 What Is Meant by Data? . . . 101
2.1.4 Extended Exercise: Interval Arithmetic . . . 104
2.2 Hierarchical Data and the Closure Property . . . 107
2.2.1 Representing Sequences . . . 109
2.2.2 Hierarchical Structures . . . 116

2.2.3 Sequences as Conventional Interfaces . . . 122
2.2.4 Example: A Picture Language . . . 134
2.3 Symbolic Data . . . 148
2.3.1 Strings . . . 148
2.3.2 Example: Symbolic Differentiation . . . 151
2.3.3 Example: Representing Sets . . . 157
2.3.4 Example: Huffman Encoding Trees . . . 166
2.4 Multiple Representations for Abstract Data . . . 174
2.4.1 Representations for Complex Numbers . . . 176
2.4.2 Tagged data . . . 179
2.4.3 Data-Directed Programming and Additivity . . . 183
2.5 Systems with Generic Operations . . . 191
2.5.1 Generic Arithmetic Operations . . . 191
2.5.2 Combining Data of Different Types . . . 197
2.5.3 Example: Symbolic Algebra . . . 204

3 Modularity, Objects, and State 219
3.1 Assignment and Local State . . . 220
3.1.1 Local State Variables . . . 221
3.1.2 The Benefits of Introducing Assignment . . . 227
3.1.3 The Costs of Introducing Assignment . . . 231
3.2 The Environment Model of Evaluation . . . 237
3.2.1 The Rules for Evaluation . . . 238
3.2.2 Applying Simple Functions . . . 241
3.2.3 Frames as the Repository of Local State . . . 244
3.2.4 Internal Declarations . . . 249
3.3 Modeling with Mutable Data . . . 253
3.3.1 Mutable List Structure . . . 254
3.3.2 Representing Queues . . . 262
3.3.3 Representing Tables . . . 267
3.3.4 A Simulator for Digital Circuits . . . 273
3.3.5 Propagation of Constraints . . . 284
3.4 Concurrency: Time Is of the Essence . . . 295
3.4.1 The Nature of Time in Concurrent Systems . . . 296
3.4.2 Mechanisms for Controlling Concurrency . . . 301
3.5 Streams . . . 313
3.5.1 Streams Are Delayed Lists . . . 314
3.5.2 Infinite Streams . . . 321
3.5.3 Exploiting the Stream Paradigm . . . 328
3.5.4 Streams and Delayed Evaluation . . . 340
3.5.5 Modularity of Functional Programs and Modularity of Objects . . . 346

4 Metalinguistic Abstraction 351
4.1 The Metacircular Evaluator . . . 354
4.1.1 The Core of the Evaluator . . . 355
4.1.2 Representing Components . . . 362
4.1.3 Evaluator Data Structures . . . 375
4.1.4 Running the Evaluator as a Program . . . 381

4.1.5 Data as Programs . . . 384
4.1.6 Internal Declarations . . . 387
4.1.7 Separating Syntactic Analysis from Execution . . . 392
4.2 Lazy Evaluation . . . 397
4.2.1 Normal Order and Applicative Order . . . 397
4.2.2 An Interpreter with Lazy Evaluation . . . 399
4.2.3 Streams as Lazy Lists . . . 406
4.3 Nondeterministic Computing . . . 409
4.3.1 Search and `amb` . . . 410
4.3.2 Examples of Nondeterministic Programs . . . 414
4.3.3 Implementing the `amb` Evaluator . . . 422
4.4 Logic Programming . . . 434
4.4.1 Deductive Information Retrieval . . . 436
4.4.2 How the Query System Works . . . 447
4.4.3 Is Logic Programming Mathematical Logic? . . . 455
4.4.4 Implementing the Query System . . . 461

5 Computing with Register Machines 485
5.1 Designing Register Machines . . . 486
5.1.1 A Language for Describing Register Machines . . . 489
5.1.2 Abstraction in Machine Design . . . 494
5.1.3 Subroutines . . . 496
5.1.4 Using a Stack to Implement Recursion . . . 500
5.1.5 Instruction Summary . . . 506
5.2 A Register-Machine Simulator . . . 506
5.2.1 The Machine Model . . . 508
5.2.2 The Assembler . . . 512
5.2.3 Generating Execution Functions for Instructions . . . 515
5.2.4 Monitoring Machine Performance . . . 523
5.3 Storage Allocation and Garbage Collection . . . 525
5.3.1 Memory as Vectors . . . 526
5.3.2 Maintaining the Illusion of Infinite Memory . . . 531
5.4 The Explicit-Control Evaluator . . . 536
5.4.1 The Dispatcher and Basic Evaluation . . . 539
5.4.2 Evaluating function applications . . . 542
5.4.3 Blocks, Assignments, and Declarations . . . 550
5.4.4 Running the Evaluator . . . 552
5.5 Compilation . . . 557
5.5.1 Structure of the Compiler . . . 560
5.5.2 Compiling Components . . . 565
5.5.3 Compiling Applications . . . 572

Foreword

Educators, generals, dieticians, psychologists, and parents program. Armies, students, and some societies are programmed. An assault on large problems employs a succession of programs, most of which spring into existence en route. These programs are rife with issues that appear to be particular to the problem at hand. To appreciate programming as an intellectual activity in its own right you must turn to computer programming; you must read and write computer programs—many of them. It doesn't matter much what the programs are about or what applications they serve. What does matter is how well they perform and how smoothly they fit with other programs in the creation of still greater programs. The programmer must seek both perfection of part and adequacy of collection. In this book the use of "program" is focused on the creation, execution, and study of programs written in a dialect of Lisp for execution on a digital computer. Using Lisp we restrict or limit not what we may program, but only the notation for our program descriptions.

Our traffic with the subject matter of this book involves us with three foci of phenomena: the human mind, collections of computer programs, and the computer. Every computer program is a model, hatched in the mind, of a real or mental process. These processes, arising from human experience and thought, are huge in number, intricate in detail, and at any time only partially understood. They are modeled to our permanent satisfaction rarely by our computer programs. Thus even though our programs are carefully handcrafted discrete collections of symbols, mosaics of interlocking functions, they continually evolve: we change them as our perception of the model deepens, enlarges, generalizes until the model ultimately attains a metastable place within still another model with which we struggle. The source of the exhilaration associated with computer programming is the continual unfolding within the mind and on the computer of mechanisms expressed as programs and the explosion of perception they generate. If art interprets our dreams, the computer executes them in the guise of programs!

For all its power, the computer is a harsh taskmaster. Its programs must be correct, and what we wish to say must be said accurately in every detail. As in every other symbolic activity, we become convinced of program truth through argument. Lisp itself can be assigned a semantics (another model, by the way), and if a program's function can be specified, say, in the predicate calculus, the proof methods of logic can be used to make an acceptable correctness argument. Unfortunately, as programs get large and complicated, as they almost always do, the adequacy, consistency, and correctness of the specifications themselves become open to

doubt, so that complete formal arguments of correctness seldom accompany large programs. Since large programs grow from small ones, it is crucial that we develop an arsenal of standard program structures of whose correctness we have become sure—we call them idioms—and learn to combine them into larger structures using organizational techniques of proven value. These techniques are treated at length in this book, and understanding them is essential to participation in the Promethean enterprise called programming. More than anything else, the uncovering and mastery of powerful organizational techniques accelerates our ability to create large, significant programs. Conversely, since writing large programs is very taxing, we are stimulated to invent new methods of reducing the mass of function and detail to be fitted into large programs.

Unlike programs, computers must obey the laws of physics. If they wish to perform rapidly—a few nanoseconds per state change—they must transmit electrons only small distances (at most $1\frac{1}{2}$ feet). The heat generated by the huge number of devices so concentrated in space has to be removed. An exquisite engineering art has been developed balancing between multiplicity of function and density of devices. In any event, hardware always operates at a level more primitive than that at which we care to program. The processes that transform our Lisp programs to "machine" programs are themselves abstract models which we program. Their study and creation give a great deal of insight into the organizational programs associated with programming arbitrary models. Of course the computer itself can be so modeled. Think of it: the behavior of the smallest physical switching element is modeled by quantum mechanics described by differential equations whose detailed behavior is captured by numerical approximations represented in computer programs executing on computers composed of …!

It is not merely a matter of tactical convenience to separately identify the three foci. Even though, as they say, it's all in the head, this logical separation induces an acceleration of symbolic traffic between these foci whose richness, vitality, and potential is exceeded in human experience only by the evolution of life itself. At best, relationships between the foci are metastable. The computers are never large enough or fast enough. Each breakthrough in hardware technology leads to more massive programming enterprises, new organizational principles, and an enrichment of abstract models. Every reader should ask himself periodically "Toward what end, toward what end?"—but do not ask it too often lest you pass up the fun of programming for the constipation of bittersweet philosophy.

Among the programs we write, some (but never enough) perform a precise mathematical function such as sorting or finding the maximum of a sequence of numbers, determining primality, or finding the square root. We call such programs algorithms, and a great deal is known of their optimal behavior, particularly with respect to the two important parameters of execution time and data storage requirements. A programmer should acquire good algorithms and idioms. Even though some programs resist precise specifications, it is the responsibility of the programmer to estimate, and always to attempt to improve, their performance.

Lisp is a survivor, having been in use for about a quarter of a century. Among the active programming languages only Fortran has had a longer life. Both languages have supported the programming needs of important areas of application, Fortran for scientific and engineering computation and Lisp for artificial intelligence. These two areas continue to be important, and their programmers are so devoted to these two languages that Lisp and Fortran may well continue in active use for at least another quarter-century.

Lisp changes. The Scheme dialect used in this text has evolved from the original Lisp and differs from the latter in several important ways, including static scoping for variable binding and permitting functions to yield functions as values. In its semantic structure Scheme is as closely akin to Algol 60 as to early Lisps. Algol 60, never to be an active language again, lives on in the genes of Scheme and Pascal. It would be difficult to find two languages that are the communicating coin of two more different cultures than those gathered around these two languages. Pascal is for building pyramids—imposing, breathtaking, static structures built by armies pushing heavy blocks into place. Lisp is for building organisms—imposing, breathtaking, dynamic structures built by squads fitting fluctuating myriads of simpler organisms into place. The organizing principles used are the same in both cases, except for one extraordinarily important difference: The discretionary exportable functionality entrusted to the individual Lisp programmer is more than an order of magnitude greater than that to be found within Pascal enterprises. Lisp programs inflate libraries with functions whose utility transcends the application that produced them. The list, Lisp's native data structure, is largely responsible for such growth of utility. The simple structure and natural applicability of lists are reflected in functions that are amazingly nonidiosyncratic. In Pascal the plethora of declarable data structures induces a specialization within functions that inhibits and penalizes casual cooperation. It is better to have 100 functions operate on one data structure than to have 10 functions operate on 10 data structures. As a result the pyramid must stand unchanged for a millennium; the organism must evolve or perish.

To illustrate this difference, compare the treatment of material and exercises within this book with that in any first-course text using Pascal. Do not labor under the illusion that this is a text digestible at MIT only, peculiar to the breed found there. It is precisely what a serious book on programming Lisp must be, no matter who the student is or where it is used.

Note that this is a text about programming, unlike most Lisp books, which are used as a preparation for work in artificial intelligence. After all, the critical programming concerns of software engineering and artificial intelligence tend to coalesce as the systems under investigation become larger. This explains why there is such growing interest in Lisp outside of artificial intelligence.

As one would expect from its goals, artificial intelligence research generates many significant programming problems. In other programming cultures this spate of problems spawns new languages. Indeed, in any very large programming task a useful organizing principle is to control and isolate traffic within the task modules via the invention of language. These lan-

guages tend to become less primitive as one approaches the boundaries of the system where we humans interact most often. As a result, such systems contain complex language-processing functions replicated many times. Lisp has such a simple syntax and semantics that parsing can be treated as an elementary task. Thus parsing technology plays almost no role in Lisp programs, and the construction of language processors is rarely an impediment to the rate of growth and change of large Lisp systems. Finally, it is this very simplicity of syntax and semantics that is responsible for the burden and freedom borne by all Lisp programmers. No Lisp program of any size beyond a few lines can be written without being saturated with discretionary functions. Invent and fit; have fits and reinvent! We toast the Lisp programmer who pens his thoughts within nests of parentheses.

—Alan J. Perlis, New Haven, Connecticut

Prefaces

Preface to the JavaScript Adaptation

You are reading the book Structure and Interpretation of Computer Programs (SICP), second edition, JavaScript adaptation. Like the original version, this book aims firstly to establish the notion that programming is a medium for communicating ideas about methodology. Programs allow their authors to describe complex processes to their readers, provided that both share mental models that underly the language in which the programs are written. Secondly it aims to describe programming as an activity to manage the complexity of software systems, by using abstraction techniques available in existing programming languages, and by inventing new languages whenever the need arises.

To succeed in these goals, the original version focuses on a minimal set of idioms of the chosen programming language, Scheme. That set of idioms is not formally taught but assimilated by students as they make progress digesting the underlying mental models and abstractions. The book does not aim to teach the language Scheme, but rather the ability to express procedural ideas in Scheme is a side effect of achieving its main goals.

Instead of Scheme, this book (SICP JS), uses JavaScript as its programming language. Just like the original, which it closely follows, the JavaScript adaptation focuses on a minimal set of idioms of the chosen language. A reader would be ill-advised to use this book in order to learn JavaScript. As a drastic example, the notion of a JavaScript object—considered one of its fundamental ingredients by any measure—is not even mentioned! The JavaScript subset used in SICP JS is designed to be just big enough to express the ideas presented in SICP with a conciseness and precision that matches the original. (The resulting sublanguage is described in detail in the web pages that accompany SICP JS.) Just like the subset of Scheme used in SICP, the subset of JavaScript used in SICP JS does not need to be formally taught; its mastery is a side effect of achieving the goals of SICP.

We sincerely hope that readers for whom this book is their first encounter with programming will use their newly gained understanding of the structure and interpretation of computer programs to study more programming languages, including Scheme and the full JavaScript language. Readers who have learned JavaScript prior to picking up SICP JS might gain new insights into the fundamental concepts that underly the language and discover how much can be achieved with so little. Readers who come to SICP JS with a knowledge of the original

SICP might enjoy seeing familiar ideas presented in a new format—and might appreciate our comparison version, also available in the web pages.

—Martin Henz and Tobias Wrigstad

Preface to the Second Edition of SICP, 1996

> Is it possible that software is not like anything else, that it is meant to be discarded: that the whole point is to always see it as a soap bubble?
>
> —Alan J. Perlis

The material in this book has been the basis of MIT's entry-level computer science subject since 1980. We had been teaching this material for four years when the first edition was published, and twelve more years have elapsed until the appearance of this second edition. We are pleased that our work has been widely adopted and incorporated into other texts. We have seen our students take the ideas and programs in this book and build them in as the core of new computer systems and languages. In literal realization of an ancient Talmudic pun, our students have become our builders. We are lucky to have such capable students and such accomplished builders.

In preparing this edition, we have incorporated hundreds of clarifications suggested by our own teaching experience and the comments of colleagues at MIT and elsewhere. We have redesigned most of the major programming systems in the book, including the generic-arithmetic system, the interpreters, the register-machine simulator, and the compiler; and we have rewritten all the program examples to ensure that any Scheme implementation conforming to the IEEE Scheme standard (IEEE 1990) will be able to run the code.

This edition emphasizes several new themes. The most important of these is the central role played by different approaches to dealing with time in computational models: objects with state, concurrent programming, functional programming, lazy evaluation, and nondeterministic programming. We have included new sections on concurrency and nondeterminism, and we have tried to integrate this theme throughout the book.

The first edition of the book closely followed the syllabus of our MIT one-semester subject. With all the new material in the second edition, it will not be possible to cover everything in a single semester, so the instructor will have to pick and choose. In our own teaching, we sometimes skip the section on logic programming (section 4.4), we have students use the register-machine simulator but we do not cover its implementation (section 5.2), and we give only a cursory overview of the compiler (section 5.5). Even so, this is still an intense course.

Some instructors may wish to cover only the first three or four chapters, leaving the other material for subsequent courses.

The World Wide Web site of MIT Press provides support for users of this book. This includes programs from the book, sample programming assignments, supplementary materials, and downloadable implementations of the Scheme dialect of Lisp.

—Harold Abelson and Gerald Jay Sussman

Preface to the First Edition of SICP, 1984

> A computer is like a violin. You can imagine a novice trying first a phonograph and then a violin. The latter, he says, sounds terrible. That is the argument we have heard from our humanists and most of our computer scientists. Computer programs are good, they say, for particular purposes, but they aren't flexible. Neither is a violin, or a typewriter, until you learn how to use it.
>
> —Marvin Minsky, "Why Programming Is a Good Medium for Expressing Poorly-Understood and Sloppily-Formulated Ideas"

"The Structure and Interpretation of Computer Programs" is the entry-level subject in computer science at the Massachusetts Institute of Technology. It is required of all students at MIT who major in electrical engineering or in computer science, as one-fourth of the "common core curriculum," which also includes two subjects on circuits and linear systems and a subject on the design of digital systems. We have been involved in the development of this subject since 1978, and we have taught this material in its present form since the fall of 1980 to between 600 and 700 students each year. Most of these students have had little or no prior formal training in computation, although many have played with computers a bit and a few have had extensive programming or hardware-design experience.

Our design of this introductory computer-science subject reflects two major concerns. First, we want to establish the idea that a computer language is not just a way of getting a computer to perform operations but rather that it is a novel formal medium for expressing ideas about methodology. Thus, programs must be written for people to read, and only incidentally for machines to execute. Second, we believe that the essential material to be addressed by a subject at this level is not the syntax of particular programming-language constructs, nor clever algorithms for computing particular functions efficiently, nor even the mathematical analysis of algorithms and the foundations of computing, but rather the techniques used to control the intellectual complexity of large software systems.

Our goal is that students who complete this subject should have a good feel for the elements of style and the aesthetics of programming. They should have command of the major techniques for controlling complexity in a large system. They should be capable of reading a 50-page-long program, if it is written in an exemplary style. They should know what not to read, and what they need not understand at any moment. They should feel secure about modifying a program, retaining the spirit and style of the original author.

These skills are by no means unique to computer programming. The techniques we teach and draw upon are common to all of engineering design. We control complexity by building abstractions that hide details when appropriate. We control complexity by establishing conventional interfaces that enable us to construct systems by combining standard, well-understood pieces in a "mix and match" way. We control complexity by establishing new languages for describing a design, each of which emphasizes particular aspects of the design and deemphasizes others.

Underlying our approach to this subject is our conviction that "computer science" is not a science and that its significance has little to do with computers. The computer revolution is a revolution in the way we think and in the way we express what we think. The essence of this change is the emergence of what might best be called *procedural epistemology*—the study of the structure of knowledge from an imperative point of view, as opposed to the more declarative point of view taken by classical mathematical subjects. Mathematics provides a framework for dealing precisely with notions of "what is." Computation provides a framework for dealing precisely with notions of "how to."

In teaching our material we use a dialect of the programming language Lisp. We never formally teach the language, because we don't have to. We just use it, and students pick it up in a few days. This is one great advantage of Lisp-like languages: They have very few ways of forming compound expressions, and almost no syntactic structure. All of the formal properties can be covered in an hour, like the rules of chess. After a short time we forget about syntactic details of the language (because there are none) and get on with the real issues—figuring out what we want to compute, how we will decompose problems into manageable parts, and how we will work on the parts. Another advantage of Lisp is that it supports (but does not enforce) more of the large-scale strategies for modular decomposition of programs than any other language we know. We can make procedural and data abstractions, we can use higher-order functions to capture common patterns of usage, we can model local state using assignment and data mutation, we can link parts of a program with streams and delayed evaluation, and we can easily implement embedded languages. All of this is embedded in an interactive environment with excellent support for incremental program design, construction, testing, and debugging. We thank all the generations of Lisp wizards, starting with John McCarthy, who have fashioned a fine tool of unprecedented power and elegance.

Scheme, the dialect of Lisp that we use, is an attempt to bring together the power and elegance of Lisp and Algol. From Lisp we take the metalinguistic power that derives from

the simple syntax, the uniform representation of programs as data objects, and the garbage-collected heap-allocated data. From Algol we take lexical scoping and block structure, which are gifts from the pioneers of programming-language design who were on the Algol committee. We wish to cite John Reynolds and Peter Landin for their insights into the relationship of Church's lambda calculus to the structure of programming languages. We also recognize our debt to the mathematicians who scouted out this territory decades before computers appeared on the scene. These pioneers include Alonzo Church, Barkley Rosser, Stephen Kleene, and Haskell Curry.
